Abstract: The purpose of this study was to determine the effect of a 12-week training program on the physical fitness of 12-year-old children. The study was conducted in a primary school in the city of Ankara, Turkey. The study group consisted of 20 children (10 boys and 10 girls) who were randomly selected from the 12-year-old children in the school. The children were divided into two groups: a control group and an experimental group. The control group did not participate in any physical activity during the 12-week period, while the experimental group participated in a 12-week training program. The training program consisted of three sessions per week, each lasting 30 minutes. The sessions included aerobic exercises, strength training, and flexibility exercises. The physical fitness of the children was measured at the beginning and at the end of the 12-week period. The measurements included heart rate, blood pressure, body mass index (BMI), and physical fitness test results. The results of the study showed that the experimental group had significantly higher heart rate, blood pressure, BMI, and physical fitness test results at the end of the 12-week period compared to the control group. These findings suggest that a 12-week training program can improve the physical fitness of 12-year-old children.
